Publisher's Disclaimer. E-publishing ahead of print is increasingly important for the rapid dissemination of science. The Early Access service lets users access peer-reviewed articles well before print / regular issue publication, significantly reducing the time it takes for critical findings to reach the research community.

These articles are searchable and citable by their DOI (Digital Object Identifier).

The Emergency Care Journal is, therefore, e-publishing PDF files of an early version of manuscripts that undergone a regular peer review and have been accepted for publication, but have not been through the typesetting, pagination and proofreading processes, which may lead to differences between this version and the final one.

The final version of the manuscript will then appear on a regular issue of the journal.

E-publishing of this PDF file has been approved by the authors.

Key words: black esophagus, Gurvits, ketoacidosis, diabetes, AEN.

Contributions: all the authors approved the final version of the manuscript, agreed to be held accountable for all aspects, and equally contributed to the work.

Conflicts of interest: the authors declare no potential conflict of interest.

Funding: none.

Availability of data and materials: all data underlying the findings are fully available upon reasonable request to the Corresponding Author.
Ethics approval and consent to participate: not necessary. The patient provided consent for access to medical records at the time of admission.

A 70-year-old Italian man presented to our emergency department for dyspnea and confusion. He was affected by diabetes mellitus type 2, but he stopped his medication 10 years before. At admission, his vital signs were blood pressure of 60/50 mmHg, heart rate of 130 bpm, peripheral oxygen saturation of 94% in the Venturi Mask FiO₂ 40%, respiratory rate of 40/min, and body temperature of 36°C. Physical examination revealed hypoperfusion with a high Mottling Score and dark stools with a positive hydrogen peroxide reaction. He denied abdominal pain, nausea, and vomiting. Laboratory findings showed leucocytosis (White Blood Cells, WBC, 31,580/mm³; N 91.6%), Hemoglobin (Hb) 14.5 g/dL, Hematocrit Test (Hct) 49%, hyperglycaemia (>700 mg/L), and normal coagulation time. Arterial blood gas documented a metabolic acidosis with pH 6.95, Partial Pressure of Carbon Dioxide (pCO₂) 27.5 mmHg, HCO₃ 7.1 mmol/L, lactate 8.14 mmol/L (normal value <2), and elevated anion gap metabolic. He was first treated with IV therapy as follows omeprazole 80 mg, tranexamic acid 1 g, Ringer acetate 1000 cc, sodium bicarbonate 8.4% 100 mg, and magnesium sulfate 2 g. Then, a continuous IV infusion of Ringer 150 mL/h and omeprazole 8 mg/h was started. An
Esophagogastroduodenoscopy (EGD) was arranged and showed circumferential blackening of the distal half of the esophagus.

**Question**

What disorder arises with this dark and black esophagus?

1. Caustic ingestion
2. Melanoma
3. Gurvits syndrome
4. Acanthosis nigricans

**Answer**

The correct diagnosis is Gurvits Syndrome also known as Acute Esophageal Necrosis (AEN) or “black esophagus” due to the associated colour change.¹ Firstly described in 1990,² AEN is a rare syndrome with a male preponderance, with an incidence four times greater than that for women and a peak incidence during the sixth decade of life.³ The prevalence is only 0.001–0.2%, while its mortality rate is up to 32%.⁴ Most of the cases are fatal due to perforation, stricture, bleeding, and infections. The etiology is not completely clear. According to a “2 hit hypothesis”, AEN can arise when an acute event occurs and causes local hypoperfusion and subsequently necrosis.⁵ Combined effects of vascular compromise, impaired defence mechanism of the esophagus, and exposure to gastric acids all contribute to AEN.⁶ The major risk factors include male sex, chronic diseases (diabetes mellitus with, hypertension, renal failure, vascular diseases), alcohol use disorder and/or recreational drug use (e.g., cocaine), malnutrition, and cancer.¹ In a recently published systemic
review, alcohol and hypertension were common comorbidities, and the overall mortality rate amounted to 32%. The most common presenting symptoms are hematemesis, shock, melena, abdominal, or substernal pain. Diagnosis is made by EGD that shows circumferential dark pigmentation of the distal third of the esophagus, which is relatively less vascular, and necrosis that stops abruptly at the gastroesophageal junction. Colour change depends on the location of the lesion, degree of necrosis, and pattern of necrosis. Biopsy is recommended but not required for a definite diagnosis. AEN has no specific treatment. Antibiotics, antifungals and nutritional support should be considered on an individual basis. Candidiasis may occur in conjunction with AEN, whilst it is not thought to be causative, treatment is considered prudent given the poor prognosis associated with this condition.

The patient was admitted to the High Dependency Unit and was treated with IV fluid and amine support, piperacillin-tazobactam, oxacillin, fluconazole, proton pump inhibitors, and total parental nutrition. One week later, an EGD showed a lighter esophageal mucosa with some white exudate spots (Figure 1). After two weeks, EGD documented fibrin deposition associated with reepithelialisation (Figure 2). The patient was released after two more weeks, when an EGD showed total resolution of AEN with no indication of stricture development or perforation (Figure 3).
