Abstract

One of the most important issues which medical science has been facing is wound healing for the tissue repair with the least complications. In this study, we aimed to isolate, purify and quantitate tannins and phenolic compounds from exocarp and pulp of fruits of Iranian pomegranate cultivars. Our findings demonstrate that the highest amount of tannin extracts from ethanol extract of the black peel exocarp was 201.76 ± 1.93. The highest amount of flavonoids from the ethanol extract of Sweet Alac exocarp was 119.69 ± 1.02 as well as antioxidant compounds activity in the exocarp and pulp showed that the highest activity is in the ethanol extract of the black peel was 95.65 ± 3.1. The total phenolic activity indicated that the Sour white peel ethanol extract has the highest phenolic activity 327.05 ± 863. Our data suggest that the ethanol extract of pomegranate exocarp has the higher amounts of tannins and flavonoids, compounds that are known to be beneficial for wound healing. Taken together, these data suggest that compounds isolated from Iranian pomegranate cultivars offer new options for managements of wound healing.

Key Words: Pomegranate cultivars, tannin, phenolic compounds, flavonoids, wound healing.

Wounds are among the most important reasons for occurring infections and diseases. Aiding fast repair of tissues and healing the wounds is a necessity in that way. Despite major progress in the treatment of surgical wounds, infection is still known as one of the most important reasons for deaths after surgery.1 Correct treatment and proper care of the wound healing with the aim of improving the speed of recovery, avoiding infections and preventing chronic wounds are always in the minds of practitioners, who use several methods to achieve these goals.2 A number of drugs and ointments are used to heal open wounds, and each of them has limitations and side effects. Iranian traditional medicine has been a very effective source of suggestions, with several medical books written on drugs for treating diseases, as seen in other traditional medicine practices.3 Many researches have recently studied traditional medicine products and their effects on wound healing and inflammation.3-5 Considering, the high number of Iranian pomegranate varieties and the importance of tannins and flavonoids in tissue repair and wound healing, identification of native pomegranate cultivars with the highest amount of tannin and phenolic compounds in the exocarp is a very promising approach. Thus, we isolated, purified and quantitated tannins and phenolic compounds from the exocarp and pulp of pomegranate fruit from several Iranian cultivars.

Materials and Methods

Iranian pomegranate cultivars

The most commercially harvested pomegranate cultivars in Iran, Sweet Alac, Sour Alac, Sour Malas, Sweet Black, Sour Summer, Sour White Peel, Sweet Saveh, Black Peel, Sweet White Peel, Agha Mohammad Ali, Sweet Shahsavar, Robab, Yousef Khani, and Sweet Aghdai were obtained from Saveh Agricultural Research Center.

Preparing extracts

To prepare the extracts from the fruit, exocarp and pulp of the pomegranates were removed. The exocarps were placed in an oven at a temperature of 75 °C for 24-48 hours to completely dry. The soaking method was used to extract tannins in this study.6

Ascorbic acid (vitamin C)

To prepare 10 grams of extract, pomegranate exocarp and pulp were dissolved in 5% metaphosphoric acid and
mixed for 4 hours. 10 milliliters of distilled water was added to the resulting solution, that was stored in a refrigerator until evaluation. To evaluate the amount of ascorbic acid (vitamin C), the 2, 6-chlorophenol endophenol method was implemented.

Total Tannin
To prepare a tannic acid solution, first, 25 mg of tannic acid was dissolved in 25 ml of sterilized distilled water and with several dilutions of tannic acid a standard curve was determined using the Broadhurst method. Total flavonoid
Total flavonoid content was determined using the aluminum chloride colorimetric method.

Antioxidant activity
Diphenyl-1-picrylhydrazyl (DPPH) standard protocol was used to evaluate the antioxidant activity.

Total phenolic compounds
Total phenolic compounds were determined according the Folin–Ciocalteu standard method.

Anthocyanin quantification
500 μL of extracts were diluted with 10 μL of hydrogen chloride 1% in methanol (1 to 99). The solution was stored in dark at room temperature for 24 hours. Then the optical absorption was determined at 530 nm. The results were reported in milligrams per 100 grams of dry pulp.

Results
Table 1 shows the results of fruit and exocarp weight and the percentage of exocarp. The results of the average efficiency for extraction in ethanol, methanol and water extracts of tannin are reported. The highest amount of tannin extracts resulted from the ethanol extract of the Black Peel exocarp (201.76 ± 1.93), and the lowest amount of tannin from the aqueous extract of Sweet Alac exocarp (119.69 ± 2.35). The highest flavonoid activity was in ethanol extract of Sweet Alac exocarp (191.69 ± 1.02), the lowest activity was in aqueous extract of Sweet Alac (39.19 ± 2.35). Our data show also that the highest activity is in the ethanol extract of the Black Peel (95.65 ± 3.1), and the minimum amount in aqueous extract of Robab pomegranate (17.7 ± 2.02). The highest total phenolic activity was present in the Sour White Peel ethanol extract (327.05 ± 863), while the aqueous extract of Robab pomegranate pulp had the lowest phenolic activity.

Evaluating the 14 Iranian native pomegranate cultivars, we found that the highest percentage of ascorbic acid is found in Sour Alac exocarp extract (97%), while the lowest amount was found in Sweet Saveh pulp extract.

Wound healing components in Iranian pomegranate cultivars
Eur J Transl Myol 29 (1): 22-26, 2019

Investigating the amount of anthocyanin in pulp and exocarp extracts the highest anthocyanin content was found in the Black Peel ethanol extract (22.52 milligrams per 100 grams) (Figure 2).

Discussion
We analyzed in this study the amount of phenolic compounds and tannins in the exocarp and pulp of 14 types of native Iranian pomegranates cultivars. Several factors, including solvent polarity affect the extraction efficiency, in particular the properties of solvents. For instance, solubility of sugar compounds in alcohols is low, but effectiveness increases with increasing extraction stages. In terms of polarity, ethanol is recognized between completely polar and nonpolar solvents. Anyhow, the most effective extraction in this study was in ethanol solvents.

Several published reports discussed antioxidant activity of different pomegranate’s extract. As to the fruit, the extract of the pomegranate’s exocarp revealed the highest antioxidant activity in laboratory, that is, in vitro, associated with higher levels of phenolic compounds. These compounds include tannins, flavonoids, alkaloids, organic acids, etc. Phenolic compounds are very strong antioxidants, that can neutralize free radicals, and their cytotoxic effects, playing an important role in human
health. Çam et al. report that in methanol extracts of pomegranate exocarp, the phenolic compounds of pomegranate exocarp extract are 258.2 mg/g, and the flavonoids are 18.1 mg/g.13 Zheng et al. report that the phenolic compounds in the ethanol extract of the pomegranate exocarp is 508.98 mg/g.14 Many authors agree that phenolic acids, flavonoids and anthocyanin compounds present in the pomegranate exocarp are responsible of the antioxidant properties of these extracts. The amount of antioxidant properties in ethanol extract of pomegranate was reported by Iqbal to be 89.23,13 while we found a slight but significant higher content 95.65 ± 3.1. Many otther researchers agree that ethanol is the best solvent for extracting antioxidant compounds from pomegranate.15 On the other hand, Nasacheva et al., 1973 showed that the exocarp of Indian native pomegranate cultivars may reach a total amount of tannin of 300 mg/g.16 As well, Sharma et al. reported that the total tannins in the exocarp of Indian pomegranate cultivars were in between 118.1 and 162.9 mg/g.17 In contrast, our study on 14 types of native Iranian pomegranates indicates that the highest amount of total tannin is found in ethanol extract of Iranian Black peel exocarp (201.76 ± 1.93).

Total amount of tannins in pomegranate depends on several factors including climate conditions of the area, species and the method of extraction. Considering that all 14 studied cultivars were grown and harvested in the same climatic, nutritional and gardening operations conditions, the difference in total amount of tannin in the fruit exocarp can be due to high genetic differences between cultivars.

In the present study, the highest amount of vitamin C was seen in Sour alac pomegranate exocarp (97%), while in the study of Talae et al. on six cultivars of native Iranian pomegranate, the highest amount of vitamin C was reported to be present in Aghae pomegranate, but in less amount.18 In addition, our study indicates that the highest amount of anthocyanin is found in the ethanol extract of black peel pomegranate exocarp, while Talae et al reported anthocyanin for Aghae pomegranate to be 27,738 milligrams per 100 milligrams of extract.18 It should be noted that, with the progress in growth of the pomegranate fruit, the ascorbic acid content significantly decreases.

As to the biological effects of the extracts, Choudhary et al., 2008 evaluated the wound healing effect of Myrobalan ethanol extract. They concluded that tannins are the most important compounds of this plant, being basically responsible for wound contraction, increased epithelialization, capillary ducts formation, and increase of fibroblasts.19 In another study researchers suggested that ethanolic extract has greater anti inflammatory effect compared to the methanolic extract. Therefore, it can be inferred that the anti inflammatory agent in R. graveolens.20

According to our study, the pomegranate exocarp contains tannin as well. The presence of this compound is the main reason for the wound healing properties of pomegranate, due to its antimicrobial properties. An extract from the whole plant can show different properties compared to the extract prepared from a specific part of the plant due to the cumulative effects of different compounds. Therefore, the findings of our study are consistent with the described mechanisms of tannins and flavonoids presented in other researches. Ruiz et al., 2007 stated that flavonoids contain anti-inflammatory cytokines, and thus weaken inflammation,23 in agreement with previous studies.22-24 In related study the result show that various parts of the pomegranate skin have different effects on wound healing in rats.25

In conclusion, since our results indicate that high levels of flavonoids are found in the ethanol extract of Sweet Alac exocarp, this extract can be used for producing anti-inflammatory drugs for wound healing starting from natural products of the traditional Iranian medicine.
