KEY WORDS: syphilis, paleopathology, Treponema pallidum, pre-Columbian hypothesis, Lombardy.

Introduction

For a long time paleopathology, origin and epidemiology of syphilis have been the object of much controversy among scholars. One of the major hypotheses proposes that syphilis originated in the New World and was introduced in Europe by Columbus's crew in the 1490s. This is supported by historical accounts indicating the rapid spread of syphilis in the 15th century. In contrast, the "pre-Columbian hypothesis" asserts that treponemal disease was present in the Old World before the 1490s, already in Greek and Roman times. This theory has been confirmed by the finding of certain venereal syphilis in England dated before 1492 (Von Hunnius et al., 2006). However, doubts about this case have been raised recently.

In fact a review of the reported cases of treponemal disease has been performed by Harper and co-workers (Harper et al., 2011). The authors of this study assert that there is still no secure evidence of syphilis in the Old World before the 1490s because though many certain cases of treponemal disease were reviewed in their article, the dates remain problematic in all of them. We present 1 case that confirms the "pre-Columbian hypothesis" and 3 other probable syphilis cases.

Materials and Methods

The 4 cases analysed come from 2 archaeological sites of northern Italy: Milan (Catholic University) and Como (Via Benzi). Both necropoli date back between the 3rd and the 5th century. Dating was based on stratigraphy, grave goods and other artefacts not associated with skeletal remains, coins and features of the graves (Niccoli, 2002; Sannazzaro, 2011). Macroscopic and microscopic standard analyses were performed for sexing (cranial and pelvic morphology, metrics), aging (dental and bone development; pubic symphysis, auricular surface) (Cattaneo et al., 2004). Palaeopathological analysis was based on the macroscopic morphological study and radiological examination, keeping in mind that lesions highly suggestive of venereal syphilis are later stages of caries sica and nodes with superficial cavitations on long bones. Skeletal evidence more specific for congenital syphilis are dental defects, such as Hutchinson's incisors. Other lesions consistent with treponemal disease are systemic periosteal reactions and sabre shins (Ortner, 2003; Harper et al., 2011).

Results

Among the 4 cases presented only one showed strong evidence for treponemal disease, more precisely congenital syphilis (Milan Catholic University, US 5880) (Cattaneo et al., 1996).

In 1 case signs observed are suggestive of venereal syphilis (Milan Catholic University, US 5290) and in 2 cases lesions are consistent with congenital syphilis (Milan Catholic University, US 2183; Como via Benzi T 17). Results, signs and their interpretation are shortly presented in Tab. 1.

The "pre-Columbian hypothesis". Moreover the presence of syphilis in Roman times also in Milan and Como has an important historical value for the repercussions that this disease could have had on the whole population. In fact syphilis is easily transmitted (sexually or transplacentally) and terminally it can causes serious neurological complications (Cattaneo et al., 2001).

In addition to classical anthropological and paleopathological analyses, we propose to start biomolecular research to confirm or disprove the diagnosis and to study the evolutionary history of *Treponema pallidum* in depth.
